

Utilización del modelo de regresión multivariada

- Cruces, Ham y Tetaz «Quality of Life in Buenos Aires Neighborhoods: Hedonic Price Regressions and the Life Satisfaction Approach”
 - Construcción de un índice de calidad de vida en base a valuaciones hedónicas.
 - Modelo incorporando valuaciones subjetivas.
- Gulyani, Sumila and Debabrata Talukdar, “Slum Real Estate: The low-quality high price puzzle in Nairobi’s slum rental market and its implications”
 - Modelo de precios hedónicos en asentamientos informales

Construcción de un índice de calidad de vida en base a valuaciones hedónicas.

- Un índice de calidad de vida puede derivarse de las valuaciones implícitas a diversos atributos urbanos.
- El modelo parte de suponer que los precios de las propiedades estarán determinados por la valuación de atributos de las propiedades en sí, pero también por un conjunto de características del barrio.

$$P_{ij} = \alpha + \sum_h \eta_h HC_{ij}^h + \sum_n \tau_n NC_{ij}^n + u_{ij}$$

- Donde i indican el hogar y j el barrio. HC (Housing Characteristics) es el conjunto de atributos del hogar (por ejemplo metros cuadrados, nro de habitaciones, si tiene jardín etc). NC (Neighborhood characteristics) es un conjunto de características del barrio.

Derivando el índice de calidad de vida (o del barrio)

- Una vez estimados los parametros del modelo obtenemos: $\hat{\eta}_h$ $\hat{\tau}_n$.
Es decir, la contribución de cada atributo en términos monetarios.
- Por lo que algo que podríamos hacer es obtener la predicción de precios correspondientes si calculamos:

$$\hat{P}_{ij} = \alpha + \sum_h \hat{\eta}_h HC_{ij}^h + \sum_n \hat{\tau}_n NC_{ij}^n$$

- Notar que para cada vivienda i podemos calcular la contribución de las características que provienen del barrio si hacemos:

$$V_{ij} = \sum_n \tau_n NC_i^n$$

- También podemos promediar estas contribuciones (todas las correspondientes a un mismo barrio) y así obtener un indicador comparable (que mide el aporte promedio).

$$QOL_j = \sum_i V_{ij} / N_j$$

Figure 8. Geographical Distribution of Price per Square Meter

Implicit Price Difference Given by Index of Quality of Life

Modelo incorporando evaluaciones subjetivas

- Puesto que la evaluación subjetiva de ciertas amenidades también podría tener un efecto más allá de lo que es posible captar por atributos objetivos, esta estimación tiene el objetivo de capturar estos atributos.

$$\log(\text{rent}) = \alpha + \sum_h \eta_h HC_h + \sum_c \theta_c OC_c + \gamma NS + \sum_n \lambda_n NE_n + \sum_s \phi_s SC_s + u$$

- Para explicar el valor de alquiler, además de las HC (Housing Characteristics) y las OC (Objective characteristics) ciertas características del barrio, se suman a esta especificación:
 - La satisfacción de los vecinos con respecto a su barrio (NS)
 - La evaluación subjetiva de ciertos atributos urbanos. (NE)
 - Características subjetivas (SC)
- A continuación mostramos las estadísticas descriptivas de cada grupo.

Modelo incorporando evaluaciones subjetivas

$$\log(\text{rent}) = \alpha + \sum_h \eta_h HC_h + \sum_c \theta_c OC_c + \gamma NS + \sum_n \lambda_n NE_n + \sum_s \phi_s SC_s + u$$

- Posible problema en este modelo: Posible colinealidad entre las variables explicativas. Las características objetivas determinan las subjetivas, etc.

Estadísticas Descriptivas

Table 6. Neighborhood Characteristics per Block with Household Survey, Geographical Module (OC variables)

	Avellaneda	Caballito	Palermo	San Cristobal	Total
